Abstract

The anisotropic Bianchi I cosmological model coupled with perfect fluid is quantized in the minisuperspace. The perfect fluid is described by using the Schutz formalism which allows to attribute dynamical degrees of freedom to matter. A Schrödinger-type equation is obtained where the matter variables play the role of time. However, the signature of the kinetic term is hyperbolic. This Schrödinger-like equation is solved and a wave packet is constructed. The norm of the resulting wave function comes out to be time dependent, indicating the loss of unitarity in this model. The loss of unitarity is due to the fact that the effective Hamiltonian is hermitian but not self-adjoint. The expectation value and the bohmian trajectories are evaluated leading to different cosmological scenarios, what is a consequence of the absence of a unitary quantum structure. The consistency of this quantum model is discussed as well as the generality of the absence of unitarity in anisotropic quantum models.

1 Introduction

One of the main hopes regarding quantum cosmology is the possibility to obtain the initial conditions that will determine the ulterior evolution of the Universe when its classical regime is reached [1, 2]. The task of obtaining a quantum cosmological scenario faces many difficulties, one of them being the absence of a natural time variable, since the

[§]e-mail: sergio@cce.ufes.br

general relativity action leads to a constrained system which is invariant under time reparametrization. There are many attempts to recover the notion of time in quantum cosmology [3]. For example, a time coordinate may be identified with the space volume, which is a growing function in an expanding universe. But, all these attempts have revealed of limited applications until now, and the problem of time in quantum cosmology remains an unsolved puzzle.

Another suggestion to incorporate a time variable in quantum cosmology is through matter fields. This proposal has been extensively discussed in reference [4]. It has been shown that a typical ordinary quantum mechanical structure can be built up: a Hilbert space, with an inner product, as well as sets of physical observables, may be identified. All analysis performed in reference [4] was made keeping the functional character of the Wheeler-DeWitt equation. A simpler consideration in the same sense was made in references [5, 6, 7, 8, 9, 10, 11], where the matter fluids were introduced with the aid of the Schutz's variables [12, 13], the Wheeler-DeWitt equation being written in the minisuperspace. The employment of the Schutz's variables permits again to identify the matter fields with time, since the associated momentum appears linearly in the Lagrangian; the restriction to minisuperspace has the advantage of allowing an explicit integration of the resulting Schrödinger-like equation.

Although of phenomenological nature, these quantum cosmological perfect fluid models in the minisuperspace are a very good laboratory in order to verify the consistency of constructing quantum cosmological models where the time variable is identified with the matter fields. Since a Schrödinger-like equation is obtained, all the machinery of ordinary quantum mechanics can be employed. In the references [5, 6, 7, 8, 9, 10, 11], this has been done for isotropic universes in many different situations, connected mainly to the nature of the matter content. In order to keep the effective Hamiltonian hermitian, the inner product in the Hilbert space has acquired an additional factor. Boundary conditions on the wave functions were imposed, assuring the hermiticity (and, at the same time, the self-adjointness) of the effective Hamiltonian operator. Wave packets were constructed from which specific predictions were obtained by computing the expectation value of the observables (in this case, the scale factor) or by evaluating the bohmian trajectories. Since the modulus of the wave function integrated in all space is time independent, both results agree. The main conclusion of those works is that the quantum model predicts a singularity-free universe which exhibits a bounce approaching the classical behaviour asymptotically.

In the present work we will attempt to extend this analysis to anisotropic cosmological models, specifically to Bianchi I models. The minisuperspace approach will be used, as well as the description of the matter fields through the Schutz's formalism. The initial aim is to verify if quantum effects may suppress the anisotropies in the same way they have suppressed the initial singularity in the isotropic case. In doing this analysis, an unexpected feature of anisotropic quantum cosmological model appears: the norm of the wave function comes out to be time dependent. Hence, the quantum model is non-unitary. This leads immediately to the question if this is a real quantum system. With a non-unitary theory a probabilistic interpretation can not be implemented, since the norm of the wave function is not a conserved quantity. At the same time, the ontological interpretation

of Bohm-de Broglie becomes doubtful, since bohmian trajectories are not conserved also. In both cases, some kind of "creation" must be admitted in order to have some quantum interpretation of the results. If an anisotropic quantum cosmological perfect fluid model is a legitimate quantizable system, some fundamental changes in quantum mechanical interpretation must be implemented.

The reason for this loss of unitarity when a simple extension from isotropic to anisotropic universes is made, is due, in our opinion, to the fact that the kinetic term of the effective Hamiltonian is not positive definite and, at the same time, due to the measure in the original gravitational action. The hyperbolic signature of the kinetic term implies that there is a whole line in the phase space where the momenta are not zero, and yet the energy is zero. Hence, the wave function need not to be zero at infinity along this line, and this implies that the probability current is non-zero at least at some points at infinity. Hence the time derivative of the norm of the wave function is not zero anymore. It is important to notice that the effective Hamiltonian is hermitian. The loss of unitarity comes from the fact that this effective Hamiltonian is not self-adjoint and it does not admit any self-adjoint extension.

This is not an artifact of the construction of the wave packet, but a general feature of anisotropic quantum models which lead to an hyperbolic signature to the kinetic term of the Hamiltonian function with an unusual measure. This suspicion is supported by the fact that when the kinetic term is made elliptic by force, the norm of the wave function becomes time independent and normal quantum framework is reestablished. But, the hyperbolicity of the Hamiltonian is not the only reason for the lack of unitarity: the specific measure in the action, due to the determinant of the metric, is also essential in the sense that its suppression by force restore also the unitarity independently of the signature of the kinetic term. Hence, the loss of unitarity is a direct consequence of a gravitational system (which leads to a non conventional measure in the inner product) which exhibits anisotropies (which leads to a hyperbolic kinetic term).

As it will be verified, the loss of unitarity leads to a fundamental discrepancy between the many-worlds interpretation (based on the Copenhagen interpretation) [14] and the Bohm-de Broglie interpretation [15, 16] of quantum mechanics. In both cases the universe exhibit a bounce. But the computation of the expectation value for the metric functions reveals a universe always isotropic; on the other hand, the bohmian trajectories reveal a universe where anisotropies are present near the bounce disappearing asymptotically. It is important to stress that such quantum Bianchi I model has been extensively studied in the literature [17, 18, 19, 20, 21]. But, in all previous work no matter field has been used, and hence no explicit time coordinate has been identified. For this reason, in our opinion, the loss of unitarity has not been remarked before.

This article is organized as follows. In the next section, we construct the Wheeler-DeWitt equation for the anisotropic perfect fluid model and we determine the wave function by using the separation of variables method. In section 3, a wave packet is constructed and its norm is shown to be time dependent. The reason for this unexpected result is discussed. In section 4, the expectation value of the scale factor and the bohmian trajectories are obtained. The discrepancy between them are settled out. In section 5 we discuss the results and present our conclusions. In the appendix we show how the equivalence

between many-worlds and dBB interpretation disappears due to the absence of unitarity in a quantum model.

2 Wheeler-DeWitt equation for an anisotropic perfect fluid model

Our starting point is the action of gravity coupled to a perfect fluid in the Schutz's formalism:

$$\mathcal{A} = \int_M d^4x \sqrt{-g} R + 2 \int_{\partial M} d^3x \sqrt{h} h_{ab} K^{ab} + \int_M d^4x \sqrt{-g} p \quad (1)$$

where K^{ab} is the extrinsic curvature, and h_{ab} is the induced metric over the three-dimensional spatial hypersurface, which is the boundary ∂M of the four dimensional manifold M ; the factor $16\pi G$ is made equal to one. The first two terms were first obtained in reference [2]; the last term of (1) represents the matter contribution to the total action in the Schutz's formalism for perfect fluids, p being the pressure, which is linked to the energy density by the equation of state $p = \alpha\rho$. In the Schutz's formalism [12, 13], the four-velocity is expressed in terms of five potentials ϵ , ζ , β , θ and S :

$$U_\nu = \frac{1}{\mu}(\epsilon_{,\nu} + \zeta\beta_{,\nu} + \theta S_{,\nu}) \quad (2)$$

where μ is the specific enthalpy. The variable S is the specific entropy, while the potentials ζ and β are connected with rotation and are absent for FRW's type models. The variables ϵ and θ have no clear physical meaning. The four velocity is subject to the condition

$$U^\nu U_\nu = 1 \quad . \quad (3)$$

The metric describing a Bianchi I anisotropic model is given by

$$ds^2 = N^2 dt^2 - \left(X(t)^2 dx^2 + Y(t)^2 dy^2 + Z(t)^2 dz^2 \right) \quad . \quad (4)$$

In this expression, $N(t)$ is the lapse function. Using the constraints for the fluid, and after some thermodynamical considerations, the final reduced action, where surface terms were discarded, takes the form

$$\begin{aligned} \mathcal{A} = \int dt \left[-\frac{2}{N} \left(\dot{X}\dot{Y}Z + \dot{X}\dot{Z}Y + \dot{Y}\dot{Z}X \right) \right. \\ \left. + N^{-1/\alpha} (XYZ) \frac{\alpha}{(\alpha+1)^{1/\alpha+1}} (\dot{\epsilon} + \theta\dot{S})^{1/\alpha+1} \exp\left(-\frac{S}{\alpha}\right) \right] \quad . \end{aligned} \quad (5)$$

At this point, is more suitable to redefine the metric coefficients as

$$X(t) = e^{\beta_0 + \beta_+ + \sqrt{3}\beta_-} \quad , \quad Y(t) = e^{\beta_0 + \beta_+ - \sqrt{3}\beta_-} \quad , \quad Z(t) = e^{\beta_0 - 2\beta_+} \quad . \quad (6)$$

Using these new variables, the action may be simplified further, leading to the gravitational Lagrangian density

$$L_G = -6 \frac{e^{3\beta_0}}{N} \{ \dot{\beta}_0^2 - \dot{\beta}_+^2 - \dot{\beta}_-^2 \} \quad . \quad (7)$$

From this expression, we can evaluate the conjugate momenta:

$$p_0 = -12 \frac{e^{3\beta_0}}{N} \dot{\beta}_0 \quad , \quad p_+ = 12 \frac{e^{3\beta_0}}{N} \dot{\beta}_+ \quad , \quad p_- = 12 \frac{e^{3\beta_0}}{N} \dot{\beta}_- \quad . \quad (8)$$

The matter sector may be recast in a more suitable form through the canonical transformations

$$T = p_S e^{-S} p_\epsilon^{-(\alpha+1)} \quad , \quad p_T = p_\epsilon^{\alpha+1} e^S \quad , \quad \bar{\epsilon} = \epsilon - (\alpha+1) \frac{p_S}{p_\epsilon} \quad , \quad \bar{p}_\epsilon = p_\epsilon \quad . \quad (9)$$

The final expression for the total Hamiltonian is

$$H = N e^{-3\beta_0} \left\{ -\frac{1}{24} (p_0^2 - p_+^2 - p_-^2) + e^{3(1-\alpha)\beta_0} p_T \right\} \quad . \quad (10)$$

The fundamental aspect of the Hamiltonian (10) to be remarked is the hyperbolic signature of the kinetic term.

The lapse function N plays the role of a Lagrangian multiplier in (10). It leads to the constraint

$$H = 0 \quad . \quad (11)$$

The quantization procedure consists in considering the Hamiltonian as an operator which is applied on a wave function

$$\hat{H}\psi = 0 \quad (12)$$

taking at the same time the momenta as operators (we use natural units where $\hbar = 1$):

$$\hat{p}_i = -i \frac{\partial}{\partial \beta_i} \quad . \quad (13)$$

Since the momentum associated to the matter degrees of freedom appears linearly in the Hamiltonian, we can identify it with a time coordinate

$$\hat{p}_T = i \frac{\partial}{\partial T} \quad . \quad (14)$$

Due to the canonical transformations employed before, this new time is related to the cosmic time t by $dt = e^{3\alpha\beta_0} dT$. In this way, we end up with the Wheeler-DeWitt equation, in the minisuperspace, for an anisotropic Universe filled with a perfect fluid:

$$\left(\frac{\partial^2}{\partial \beta_0^2} - \frac{\partial^2}{\partial \beta_+^2} - \frac{\partial^2}{\partial \beta_-^2} \right) \psi = -24i e^{3(1-\alpha)\beta_0} \frac{\partial \psi}{\partial T} \quad . \quad (15)$$

The wave function Ψ must obey the following boundary conditions:

$$\Psi'|_{\beta_i \rightarrow \pm\infty} = \kappa \Psi|_{\beta_i \rightarrow \pm\infty} \quad , \quad (16)$$

with $\kappa \in (-\infty, \infty]$, β_i denoting the dynamical variables. These boundary conditions are established by requiring that the Hamiltonian be hermitian. For $\kappa = 0$ and ∞ , the boundary conditions are $\Psi'|_{\beta_i \rightarrow \pm\infty} = 0$ and $\Psi|_{\beta_i \rightarrow \pm\infty} = 0$, respectively. As it will be seen later, in spite of being hermitian, the effective Hamiltonian is not self-adjoint and does not admit any self-adjoint extension. This will lead to the loss of unitarity. A more detailed discussion on the self-adjoint properties of the operators in quantum cosmology with perfect fluid, in a situation very close to the present one, is given in references [7, 11]. A rigorous mathematical discussion is given in reference [22].

Now, our goal is to solve (15) and to construct the corresponding wave packet. To do so, we use the separation of variable's method. First, we write the wave function as

$$\psi(\beta_0, \beta_+, \beta_-, T) = \phi(\beta_0, \beta_+, \beta_-) e^{-iET} \quad , \quad (17)$$

leading to the equation

$$\left(\frac{\partial^2}{\partial \beta_0^2} - \frac{\partial^2}{\partial \beta_+^2} - \frac{\partial^2}{\partial \beta_-^2} \right) \phi = -24E e^{3(1-\alpha)\beta_0} \phi \quad . \quad (18)$$

The function ϕ is then written as

$$\phi(\beta_0, \beta_+, \beta_-) = \Upsilon_0(\beta_0) \Upsilon_+(\beta_+) \Upsilon_-(\beta_-) \quad , \quad (19)$$

leading to the equation

$$\frac{\partial_0^2 \Upsilon_0}{\Upsilon_0} + 24E e^{3(1-\alpha)\beta_0} - \frac{\partial_+^2 \Upsilon_+}{\Upsilon_+} - \frac{\partial_-^2 \Upsilon_-}{\Upsilon_-} = 0 \quad (20)$$

where we have simplified in an obvious way the notation for the partial derivatives. The solutions for the functions $\Upsilon_{\pm}$ are

$$\Upsilon_{\pm} = C_{\pm} e^{ik_{\pm}\beta_{\pm}} \quad , \quad (21)$$

where $C_{\pm}$ are constants and $k_{\pm}$ are the separation parameters. These separation parameters must be real otherwise the wave function is not normalizable.

The equation determining the behaviour of Υ_0 takes then the form,

$$\Upsilon_0'' + \left(24E e^{3(1-\alpha)\beta_0} + (k_+^2 + k_-^2) \right) \Upsilon_0 = 0 \quad , \quad (22)$$

the primes meaning derivatives with respect to β_0 . It is easily to see that the parameter E must be positive. The previous equation can be solved through the redefinitions

$$a = e^{\beta_0} \quad , \quad y = a^r \quad , \quad r = \frac{3}{2}(1-\alpha) \quad . \quad (23)$$

after what (22) takes the form of a Bessel's equation:

$$\ddot{\Upsilon}_0 + \frac{\dot{\Upsilon}_0}{y} + \left(\frac{24E}{r^2} + \frac{k^2}{r^2} \frac{1}{y^2} \right) \Upsilon_0 = 0 \quad (24)$$

where $k^2 = k_+^2 + k_-^2$ and the dots are derivatives with respect to y . The solution is

$$\Upsilon_0 = C_1 J_\nu \left(\frac{\sqrt{24E}}{r} a^r \right) + C_2 J_{-\nu} \left(\frac{\sqrt{24E}}{r} a^r \right) \quad , \quad (25)$$

with $\nu = ik/r$, $C_{1,2}$ being integration constants.

The final expression for the wave function is then

$$\Psi = e^{i(k_+\beta_+ + k_-\beta_-)} \left[\bar{C}_1 J_\nu \left(\frac{\sqrt{24E}}{r} a^r \right) + \bar{C}_2 J_{-\nu} \left(\frac{\sqrt{24E}}{r} a^r \right) \right] e^{-iET} \quad (26)$$

where $\bar{C}_{1,2}$ are combinations of the preceding integration constants.

3 The wave packet: Loss of unitarity

We want now to construct a superposition of the solutions (26), generating a regular wave packet. In principle, this can be achieved by considering the integration constants as gaussian functions of the parameters $k_\pm$ and E . The general case constitutes a hard problem from the technical point of view. We may consider, for simplicity, the final wave function independent of one of the variables $\beta_\pm$, which amounts to fix one the corresponding parameters k_+ or k_- equal to zero. From here on we will consider $k_- = 0$. Notice that the final results would be the same if we had imposed $k_+ = 0$ and $k_- \neq 0$. Hence, even if the anisotropic models are not analyzed in all their generality, a large class of them is covered in what follows.

Fixing $k_- = 0$, the wave packet is given by

$$\Psi = \int e^{ik_+\beta_+} \left\{ \bar{C}_1 J_\nu \left(\frac{\sqrt{24E}}{r} a^r \right) + \bar{C}_2 J_{-\nu} \left(\frac{\sqrt{24E}}{r} a^r \right) \right\} e^{-iET} dk_+ dE \quad . \quad (27)$$

In principle, in the expression for ν it appears the modulus of k_+ while in the first exponential in (27) we have $-\infty < k_+ < +\infty$. We will consider a superposition of both Bessel's functions in such a way that the expression for the wave packet may be written as

$$\Psi = \int_{-\infty}^{+\infty} \int_0^\infty A(k_+, q) e^{ik_+\beta_+} J_\nu \left(q a^r \right) e^{-iq^2 T} dk_+ dq \quad , \quad (28)$$

with $q = \frac{\sqrt{24E}}{r}$ and

$$A(k_+, q) = e^{-\gamma k_+^2} q^{\nu+1} e^{-\lambda q^2} \quad . \quad (29)$$

In this case, the integrals can be explicitly calculated, leading to the wave packet

$$\Psi = \frac{1}{B} \sqrt{\frac{\pi}{\gamma}} \exp \left[-\frac{a^{2r}}{4B} - \frac{(\beta_+ + C(a, B))^2}{4\gamma} \right] \quad (30)$$

where

$$B = \lambda + isT \quad , \quad C(a, B) = \ln a - \frac{2}{3(1-\alpha)} \ln 2B \quad , \quad s = -\frac{3(1-\alpha)^2}{32} \quad . \quad (31)$$

Notice that the wave packet given by (30) is square integrable, and it vanishes in the extremes of the interval of validity of the variables $a = e^{\beta_0}$ and β_+ , except along the line $\beta_0 = -\beta_+$ where it takes a constant value, being consequently regular as it is physically required. The wave packet (30) is indeed a solution of the equation (15), as it can be explicitly verified, and it obeys the boundary conditions fixed before. If we discard the terms corresponding to the variable β_+ (connected with k_+), the wave packet for the isotropic case [10] is reobtained.

The main point to be remarked now is that the norm of (30) is time dependent. Using the definition $a = e^{\beta_0}$ and integrating in β_+ and a we obtain

$$\int_0^\infty \int_{-\infty}^\infty a^{2-3\alpha} \Psi^* \Psi \, da \, d\beta_+ = \frac{\sqrt{2\gamma\pi}}{3(1-\alpha)} \frac{2}{\lambda} F(T) \quad . \quad (32)$$

where

$$F(T) = \exp\left(\frac{C_I^2}{2\gamma}\right) \quad , \quad (33)$$

and

$$C(a, B) = C_R + iC_I \quad , \quad C_R = \ln a - \frac{1}{3(1-\alpha)} \ln 4B^* B \quad , \quad C_I = \frac{-2}{3(1-\alpha)} \arctan\left(\frac{sT}{\lambda}\right) \quad . \quad (34)$$

The norm of the wave function is time dependent. Hence, the quantum model is not unitary.

The absence of unitarity may be understood by inspecting again the wave packet (30). In fact, this wave packet goes to zero at infinity, excepted along the line $\beta_0 = -\beta_+$, where it takes a constant value at infinity. This does not spoil the regularity of the wave packet; in particular, it remains finite when integrated in all space and specific boundary conditions are obeyed. But, this leads, at the same time, to an anomaly in the infinity boundary. The reason for this anomaly may be understood by analysing again the Schrödinger-like equation (15). Notice that, after decomposing it into stationary states, the energy E is zero along the whole line $\beta_0 = -\beta_+$. Along this line, the wave function need not to vanish.

It would be expected that a hermitian Hamiltonian operator should always lead to a unitary quantum system, since the Hamiltonian operator is responsible for the time evolution of the quantum states. The problem here relies on the fact that, in spite of being hermitian, the Hamiltonian effective operator

$$H_{eff} = e^{-3(1-\alpha)} \left\{ \partial_0^2 - \partial_+^2 - \partial_-^2 \right\} \quad (35)$$

is not self-adjoint. This means that $H^\dagger = H$ but the domain of $H^\dagger$ is not the same as the domain of H , and the conservation of the norm becomes senseless [23].

In order to verify if an operator is self-adjoint or not, we must compute the so-called deficiency indices $n_{\pm}$ which are the dimensions of the linear independent square integrable solutions of the indicial equation

$$H\phi = \pm i\phi \quad . \quad (36)$$

Using the effective Hamiltonian (35), the solutions of the indicial equations are ¹

$$\phi_+ = c_1 J_{\nu}(y) + c_2 J_{-\nu}(y) \quad , \quad (37)$$

$$\phi_- = c_3 K_{\nu}(y) + c_4 I_{\nu}(y) \quad , \quad (38)$$

where $\nu = ik/r$ and $y = \sqrt{i/r^2} a^r$, a and r having the same definitions as before. It is easy to see that $J_{\pm\nu}(y)$ and $I_{\nu}(y)$ are not square integrable solutions while $K_{\nu}(y)$ is. Hence, $n_+ = 0$ and $n_- = 1$ and, as explained in [23], the effective Hamiltonian operator is not self-adjoint and does not admit any self-adjoint extension. Notice that changing arbitrarily the signature in (35) or suppressing the unusual measure, the deficiency indices become $n_+ = n_- = 0$ and the effective Hamiltonian becomes self-adjoint.

It is important to remark also that, due to hyperbolic character of the Hamiltonian, the energy E may take negative values. Hence, we may expect that this system is unstable since the energy is not bound below. However, it is possible to consider a kind of "Dirac sea" hypothesis, with all negative energy state filled, and to take effectively into account only positive energy states.

To support the idea that this anomaly is due to the hyperbolic signature in the kinetic term in (15), together with the unusual measure, let us change it to an elliptic signature by force. In doing so, the main change in the wave functions (55) is that the order of the Bessel function becomes real: $\nu = |k|$. We keep only the Bessel function of positive order because it does not diverge as $a \rightarrow 0$. In evaluating the norm of the wave function, we consider the same superposition factor as in (29) and we first integrate on the parameter q , obtaining,

$$\Psi = \frac{\Psi_0}{B} \exp \frac{a^{2r}}{4B} \int_0^{\infty} \exp \left[-\gamma k^2 + \left(C(a, B) + i\beta_+ \right) k \right] dk \quad . \quad (39)$$

Now we write

$$N = \int_{-\infty}^{+\infty} \int_0^{\infty} a^{2-3\alpha} \Psi^* \Psi da d\beta_+ \quad , \quad (40)$$

and we integrate first in β_+ and then in a . The unusual measure in the integrals is due to the requirement that the reduced Hamiltonian in (15) must be hermitian [10, 11]. The final result is

$$N = \Psi_0'^2 \int_0^{\infty} 2^{k/r} \Gamma(1 + k/r) e^{-2\gamma k^2} \quad , \quad (41)$$

where $\Gamma(x)$ is the gamma function, and Ψ_0' is a new constant. The norm of the wave function is finite and, more important, time independent. The same occurs if instead the measure is suppressed.

¹It must be remarked that in finding the solutions, we supposed the system to be independent of the variable β_- and we perform a plane wave expansion in the variable β_+ . In this sense, we considered just a one-dimensional system depending on the variable β_0 with a parameter k . However, the conclusions do not depend on these considerations and we could consider at least a two-dimensional system by, for example, performing a gaussian superposition in the parameter k .

4 The scenario for the Universe

The fact that the quantum cosmological perfect fluid model leads to a non-unitary quantum system implies in principle that no usual quantum interpretation can be applied to it, unless we allow creation of universes. In what follows we will adopt the point of view that this is a legitimate quantum system which ask for a convenient framework interpretation. Hence, we will try to extract previsions for the evolution of such a universe using the many-worlds and dBB interpretations scheme. Of course, these interpretations scheme must be enlarged in order to incorporate non-unitary quantum system. It is not sure that this can be done consistently. However, this very important conceptual problem is outside the purpose of the present work. Here, in particular we will show that the many-worlds and Bohm-de Broglie interpretations leads to different results. This is due to the lack of unitarity as it is explained in the appendix.

Before to do this, let us just recall the classical solutions for the Bianchi I cosmological model with a barotropic perfect fluid described by $p = \alpha\rho$. For the time parametrization $dt = a^{3\alpha}dT$, t being the cosmic time, the functions X , Y , and Z admit the solution

$$X(T) = e^{\beta_0 + \beta_+ + \sqrt{3}\beta_-} = X_0 \left(T + c \right)^{\frac{1+2s_1}{3(1-\alpha)}} \left(T - c \right)^{\frac{1-2s_1}{3(1-\alpha)}} , \quad (42)$$

$$Y(T) = e^{\beta_0 + \beta_+ - \sqrt{3}\beta_-} = Y_0 \left(T + c \right)^{\frac{1+2s_2}{3(1-\alpha)}} \left(T - c \right)^{\frac{1-2s_2}{3(1-\alpha)}} , \quad (43)$$

$$Z(T) = e^{\beta_0 - 2\beta_+} = Z_0 \left(T + c \right)^{\frac{1+2s_3}{3(1-\alpha)}} \left(T - c \right)^{\frac{1-2s_3}{3(1-\alpha)}} , \quad (44)$$

where c is constant, and s_1 , s_2 and s_3 are parameters such that

$$s_1 + s_2 + s_3 = 0 \quad , \quad s_1^2 + s_2^2 + s_3^2 = 6 \quad . \quad (45)$$

Notice that there is an initial singularity, near which the Universe is very anisotropic, becoming isotropic asymptotically.

Let us return now to the computation of the quantum scenario through the use of the many-worlds and ontological interpretations of quantum mechanics.

4.1 Expectation values of the dynamical variables

Given the wave function Ψ , the expectation value of a variable β_i is obtained in the usual way:

$$\langle \beta_i \rangle = \frac{\int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} e^{3(1-\alpha)\beta_0} \Psi^* \beta_i \Psi d\beta_0 d\beta_+}{\int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} e^{3(1-\alpha)\beta_0} \Psi^* \Psi d\beta_0 d\beta_+} . \quad (46)$$

For $\beta_i = \beta_0$ in (46) we find for the numerator:

$$\int_0^\infty a^{2-3\alpha} \Psi^* \Psi \ln a \, da \, d\beta_+ = \frac{F(T) \sqrt{2\gamma\pi}}{9(1-\alpha)^2} \frac{2}{\lambda} \left\{ \ln \left(\frac{2B^* B}{\lambda} \right) + n \right\} , \quad (47)$$

where we have noted

$$n = \int_0^\infty \exp(-u) \ln u \, du \sim -0.577 \quad , \quad u = \frac{\lambda}{2B^*B} a^{3(1-\alpha)} \quad . \quad (48)$$

Hence,

$$\langle \beta_0 \rangle = \frac{1}{3(1-\alpha)} \left\{ \ln \left(\frac{2|B|^2}{\lambda} \right) + n \right\} \quad . \quad (49)$$

This result leads to

$$e^{\langle \beta_0 \rangle} = (XYZ)^{1/3} = a_0 \left[1 + \frac{s^2 T^2}{\lambda^2} \right]^{\frac{1}{3(1-\alpha)}} \quad , \quad (50)$$

where a_0 is a constant. This is the same result as in the isotropic case [10]. Consequently, the space volume evolves as in the corresponding isotropic case.

The anisotropies are represented by the function β_+ , whose expectation value will be computed in what follows. We will evaluate now the numerator of (46) with $\beta_i = \beta_+$. Integrating in β_+ and expressing β_0 in terms of a as before, we find:

$$\int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} e^{3(1-\alpha)} \Psi^* \beta_+ \Psi \, d\beta_0 \, d\beta_+ = -\sqrt{\pi} \left\{ I_1 - \frac{\ln(4B^*B)}{3(1-\alpha)} I_2 \right\} \frac{F(T)}{B^*B} \quad , \quad (51)$$

$$I_1 = \int_0^\infty a^{2-3\alpha} \exp \left\{ -\lambda \frac{a^{3(1-\alpha)}}{2B^*B} \right\} \ln a \, da \quad , \quad I_2 = \int_0^\infty a^{2-3\alpha} \exp \left\{ -\lambda \frac{a^{3(1-\alpha)}}{2B^*B} \right\} da \quad (52)$$

The integrals I_1 and I_2 take the form,

$$I_1 = \frac{1}{9(1-\alpha)^2} \left[\frac{2B^*B}{\lambda} \right] \left[n + \ln \left(\frac{2B^*B}{\lambda} \right) \right] \quad , \quad I_2 = \frac{1}{3(1-\alpha)} \frac{2B^*B}{\lambda} \quad . \quad (53)$$

We find finally

$$\langle \beta_+ \rangle = \frac{1}{3(1-\alpha)} \left\{ \ln(2\lambda) - n \right\} \quad . \quad (54)$$

The expectation value of β_+ does not depend on time. Consequently, the predicted result for the evolution of the Universe in this case is the same as in the isotropic case: there is no anisotropy during all the evolution of the Universe. A similar computation shows that $\langle \beta_+^2 \rangle$ is also time independent. The cosmological scenario is really isotropic.

4.2 Computation of the bohmian trajectories

The result found in the last section indicates no trace of the anisotropies existing in the classical model in the corresponding quantum analysis. We will evaluate the bohmian trajectories which determine the behaviour of a quantum system in the ontological interpretation of quantum mechanics.

In the ontological interpretation of quantum mechanics, the wave function is written as

$$\Psi = \Sigma \exp(i\Theta) \quad , \quad (55)$$

where Σ is connected with the amplitude of the wave function, and Θ to its phase. When (55) is inserted into the Schrödinger's equation, the real and imaginary parts of the resulting expression leads to the conservation of probability and to a Hamilton-Jacobi's equation supplemented by a term which is identified as the quantum potential, which leads to the quantum effects distinguishing the quantum trajectories from the classical ones.

In this formulation of quantum mechanics, the trajectories (which are real trajectories) corresponding to a dynamical variable q with a conjugate momentum p_q are given by

$$p_q = \frac{\partial \Theta}{\partial q} \quad . \quad (56)$$

The ontological formulation of quantum mechanics leads to a natural identification of a time coordinate, what is very important for quantum cosmology where in general there is no explicit time coordinate.

Let us consider the wave function (30). Putting in the form (55), the phase reads,

$$\Theta(\beta_0, \beta_+, T) = -\arctan\left(\frac{sT}{\lambda}\right) + \frac{sTa^{3(1-\alpha)}}{4B^*B} - \frac{C_I}{2\gamma}(\beta_+ + C_R) \quad , \quad (57)$$

where all quantities are defined as before. The conjugate momenta associated to the dynamical variables β_0 and β_+ read

$$p_0 = -12a^{2-3\alpha}\dot{a} \quad , \quad p_+ = 12a^{3(1-\alpha)}\dot{\beta}_+ \quad , \quad (58)$$

where we have explicitly used the time parametrization such that the lapse function is given by $N = a^{3\alpha}$. The bohmian trajectories are then given by the expressions

$$-12a^{2-3\alpha}\dot{a} = 3(1-\alpha)\frac{sT}{4B^*B}a^{3(1-\alpha)} - \frac{C_I}{2\gamma} \quad , \quad (59)$$

$$12a^{3(1-\alpha)}\dot{\beta}_+ = -\frac{C_I}{2\gamma} \quad , \quad (60)$$

dots representing derivatives with respect to T . Combining (59,60), we find

$$-12a^{2-3\alpha}\dot{a} = 3(1-\alpha)\frac{sT}{4B^*B}a^{3(1-\alpha)} + 12a^{3(1-\alpha)}\dot{\beta}_+ \quad . \quad (61)$$

This last equation leads after integration to the expression

$$a e^{\beta_+} = D \left[\lambda^2 + s^2 T^2 \right]^{\frac{1}{3(1-\alpha)}} \quad . \quad (62)$$

Reinserting the relation in the equations (59,60) we can obtain the following solutions to a and β_+ :

$$a = \left(\frac{-1}{24s\lambda\gamma} \right)^{\frac{1}{3(1-\alpha)}} \left[\lambda^2 + s^2 T^2 \right]^{\frac{1}{3(1-\alpha)}} \left[\arctan^2\left(\frac{sT}{\lambda}\right) + E \right]^{\frac{1}{3(1-\alpha)}} \quad , \quad (63)$$

$$\beta_+ = -\frac{1}{3(1-\alpha)} \ln \left\{ \arctan^2\left(\frac{sT}{\lambda}\right) + E \right\} + \ln \left\{ \left[-24s\lambda\gamma \right]^{\frac{1}{3(1-\alpha)}} \right\} + \ln D \quad , \quad (64)$$

where E and D are integration constants. Remember that $s < 0$.

In opposition to the expressions obtained for the expectation values of β_0 (which is connected to a) and β_+ in the preceding subsection, the bohmian trajectories predict an anisotropic Universe. Until this point, this strange discrepancy is not so catastrophic: in order the bohmian trajectories coincide with the results for the expectation value for some quantity, the integration constants that appear in the former must be averaged over an initial distribution given by the modulus of the wave function at $T = 0$. At $T = 0$, we have

$$a(T = 0) = \left(\frac{-\lambda E}{24s\gamma} \right)^{\frac{1}{3(1-\alpha)}}, \quad (65)$$

$$\beta_+(T = 0) = \ln \left\{ \left[\frac{-24s\lambda\gamma D^{3(1-\alpha)}}{E} \right]^{\frac{1}{3(1-\alpha)}} \right\}. \quad (66)$$

Hence,

$$\mathcal{R}_i = \Psi^* \Psi|_{T=0} = \frac{\pi}{\lambda^2 \gamma} e^{\frac{E}{48s\gamma} - \frac{1}{18(1-\alpha)^2 \gamma} \ln^2 \left[\frac{D^{3(1-\alpha)}}{4} \right]} \quad (67)$$

For β_0 and β_+ the average on the initial conditions leads to the integral expressions

$$\bar{\beta}_0(T) = \int_0^\infty \int_0^\infty e^{3(1-\alpha)\beta_0^i} \mathcal{R}_i \beta_0(T) d\beta_0^i d\beta_+^i, \quad (68)$$

$$\bar{\beta}_+(T) = \int_0^\infty \int_0^\infty e^{3(1-\alpha)\beta_+^i} \mathcal{R}_i \beta_+(T) d\beta_0^i d\beta_+^i, \quad (69)$$

where β_0^i and β_+^i denote the initial values of the metric functions. In the isotropic case [10] the expression corresponding to the above ones leads to a perfect agreement between many-worlds and dBB interpretations. These expressions can be recast in the following form:

$$\bar{\beta}_0(T) = \frac{1}{9(1-\alpha)^2} \frac{\Psi_0^2}{-24s\gamma\lambda} \int_0^\infty \int_0^\infty \exp\left(\frac{y}{48s\gamma}\right) \exp\left(-\frac{(\ln x)^2}{2\gamma}\right) \times \ln \left\{ (\lambda^2 + s^2 T^2) \left[\left(\arctan(sT/\lambda) \right)^2 + y \right] \left(-\frac{1}{48s\gamma\lambda} \right) \right\} \frac{dx dy}{x}, \quad (70)$$

$$\bar{\beta}_+(T) = -\frac{1}{9(1-\alpha)^2} \frac{\Psi_0^2}{-24\gamma s\lambda} \int_0^\infty \int_0^\infty \exp\left(\frac{y}{48s\gamma}\right) \exp\left(-\frac{(\ln x)^2}{2\gamma}\right) \times \ln \left\{ \frac{[\arctan(sT/\lambda)]^2 + y}{-96\gamma s\lambda x^{3(1-\alpha)}} \right\} \frac{dy dx}{x}, \quad (71)$$

where $x = 4^{-\frac{1}{3(1-\alpha)}} D$ and $y = E$. The variables x and y were restricted to positive values in order to assure that the metric functions are real. Even if the integrals (70,71) seem to admit no simple closed expressions, it is evident that they are time dependent.

5 Conclusions

It is generally expected that quantum effects in the very early universe may furnish the set of initial conditions which will determine the subsequent evolution of the Universe

when its classical phase is reached. By initial conditions we mean here the isotropy and homogeneity. Moreover, it is also expected that those quantum effects may lead to the avoidance of the initial singularity, one of the major problems of the standard cosmological model. In this work we have tried to analyse the possibility that quantum effects can suppress initial anisotropies. Specifically, we have studied a Bianchi I model with a perfect fluid, with an isotropic pressure, employing the Schutz's description for perfect fluids. This problem has for us two main interests: first, it adds more degrees of freedom with respect to the isotropic model, since now we have four independent variables instead of just two; second, it permits to verify if anisotropies in the early Universe disappear in the quantum model, as it happens with the initial singularity for the corresponding isotropic one. The employment of Schutz's formalism for the description of the perfect fluid present in the model allows us to identify quite naturally a time coordinate associated to the matter degrees of freedom, since the canonical momentum corresponding to the matter variables appears linearly in the Hamiltonian. Hence, the Wheeler-DeWitt equation can be reduced to a Schrödinger-like equation in terms of three dynamical variables related to the metric function, β_0 , β_+ and β_- . In order to treat the problem analytically, we have restricted the problem to the special case that the wave function is independent of one of the variables, namely β_- .

The resulting Schrödinger-like equation has a hyperbolic signature in the kinetic term. This means that a state of zero energy is possible along an infinite line where $p_0 = p_+$ or, equivalently, $\beta_0 = \beta_+$. This leads to an anomaly in the boundary at infinity which, however, does not spoil the regularity of the wave function. But as consequence, the resulting quantum system is not unitary anymore. The reason for this loss of unitarity is the absence of a self-adjoint extension for the hermitian effective Hamiltonian (35). The lack of self-adjointness in this model is due both to the hyperbolic signature (which is a consequence of treating an anisotropic quantum cosmological model) and due to the presence of a non-trivial measure in the original Hamiltonian (10) (which is consequence of treating a gravitational system), as a detailed inspection of the computation of the deficiency indices reveals. The loss of unitarity leads to a discrepancy between the many-worlds and Bohm-de Broglie interpretations of quantum mechanics. Notice that if we go back to the isotropic model, where there is no hyperbolicity anymore, but yet an unusual measure, the unitarity is restored. It is important to remark that, in our opinion, the loss of unitarity pointed out here in anisotropic models has no relation with the description for the matter fluid, since the hyperbolicity of the kinetic term and the unusual measure appear already in the pure gravitational sector.

In order to verify this explicitly, we have solved the Wheeler-DeWitt equation in the minisuperspace. A wave packet was constructed being regular in the sense that it is square integrable. Using this wave packet, we have determined the behaviour of the metric functions using first the many-worlds interpretation of quantum mechanics, which implies to compute the expectation value of those functions. We found that there is no trace of anisotropies at any moment: the expectation value of the function β_+ is constant while the expectation value of β_0 has essentially the same expression as in the isotropic version of this problem. All the features of this model are the same as in the isotropic case. Later, we have determined the behaviour of metric functions employing the

ontological interpretation of quantum mechanics, determining the bohmian trajectories. In this case the function β_+ is no longer a constant, and an initial anisotropic Universe is predicted. Asymptotically, it becomes isotropic like in the classical case. This result is maintained even after the averaging on the initial conditions. As it is well known [15, 16] the bohmian trajectories should lead to the same results that are obtained computing the expectation values after averaging on the initial conditions. This equivalence does not occur for the anisotropic Bianchi I cosmological model because the equivalence between both interpretations is valid only for unitary system.

Let us now precise in another way that the loss of unitarity is due to the anomaly at the boundary at infinity generated by the hyperbolic signature of the kinetic term. Writting the wave function as in (55), we obtain the expression

$$12e^{3(1-\alpha)\beta_0}\frac{\partial}{\partial t}\Sigma^2 = \frac{\partial}{\partial\beta_0}\left(\Sigma^2\frac{\partial}{\partial\beta_0}\Theta\right) - \frac{\partial}{\partial\beta_+}\left(\Sigma^2\frac{\partial}{\partial\beta_+}\Theta\right) \quad (72)$$

which should express the conservation of probability. Integrating in β_0 and β_+ does not lead to the vanishing of the integrated left hand side, since the norm of the wave function is time dependent. The term in the right-hand side can be converted to a surface integral at infinity. The currents are zero at infinity excepted along the line $\beta_0 = -\beta_+$, and hence the right hand side also does not vanish.

The question resulting from the analysis made above is if it is possible to consider seriously such quantum cosmological perfect fluid model. In principle, the answer, in our opinion, must be positive, since this system is a natural extension of the corresponding isotropic case, where everything is well definite. But, in order to take seriously such model, the usual interpretation scheme of quantum mechanics must be enlarged in order to take into account creation/annihilation of probabilities and bohmian trajectories. In what concerns cosmology this perhaps may be done since these creation/annihilation refer to disconnected universes. But, this remains an open issue, and what we may assert at the moment is that the loss of unitarity is a general feature of quantum system where the signature of the kinetic term is hyperbolic as it happens with anisotropic cosmological models. Moreover, since the predictions for the evolution of the universe using the many-worlds or the ontological interpretations do not coincide, one of them must be more suitable for implementation of this enlarged interpretation of quantum mechanics. Notice, finally, that the loss of unitarity appears already when quantum fields are quantized in space-times with closed timelike curves [24]. But this represents another context since the space-time itself remains classical.

A Conditions for the equivalence between many-worlds and dBB interpretations

Let us for simplicity consider a one dimensional quantum mechanical system:

$$-\frac{\partial^2}{\partial x^2}\Psi + V(x)\Psi = i\frac{\partial}{\partial t}\Psi \quad . \quad (73)$$

From this expression we obtain

$$\frac{\partial \mathcal{R}}{\partial t} = -\frac{\partial}{\partial x}\left(\mathcal{R}\frac{\partial}{\partial x}\theta\right) \quad , \quad (74)$$

where we have used (55) and we have defined $\mathcal{R} = \Psi^*\Psi$. The expectation value and the averaged bohmian trajectories are given by

$$\langle x \rangle_C = \frac{\int_{-\infty}^{\infty} \mathcal{R} x dx}{\int_{-\infty}^{\infty} \mathcal{R} dx} \quad , \quad \bar{x}_B = \int_{-\infty}^{\infty} \mathcal{R}_0 x(t) dx_0 \quad (75)$$

where C and B stand for "Copenhagen" and "Bohm", respectively. The subscript in the second integral indicates that the quantities must be evaluated at $t = 0$. Also in this second integral the function $x(t)$ is obtained by integrating the bohmian trajectories $\dot{x}(t) = d\Theta/dx$. If the norm of the wave function is made equal to one in $t = 0$, those quantities are identical at this moment.

To show that they are the same for all time, we must just show that their derivatives are the same for any value of t . Taking the derivative and using the expression for the current in the first integral and the expression for the bohmian trajectories in the second one, we obtain

$$\frac{d}{dt} \langle x \rangle_C = \int_{-\infty}^{\infty} \mathcal{R} \frac{\partial \Theta}{\partial x} dx \quad , \quad \frac{d}{dt} \bar{x}_B = \int_{-\infty}^{\infty} \mathcal{R}_0 \frac{\partial \Theta}{\partial x} dx_0 \quad , \quad (76)$$

where we have assumed the norm of the wave function equal to one. Integrating the expression for the current, we have that the derivative of the norm of the wave function is zero. Hence, it has the same value at any time, from which

$$\int_{-\infty}^{\infty} \mathcal{R}_t dx_t = \int_{-\infty}^{\infty} \mathcal{R}_0 dx_0 \quad . \quad (77)$$

This implies that, after a changing of variable in the second integral,

$$\mathcal{R}_0 \frac{dx_0}{dx_t} = \mathcal{R}_t \quad . \quad (78)$$

Inserting this in (76) we find that the derivative of expectation value and of the averaged bohmian trajectories are the same for any value of t . Since, they were equal for $t = 0$, both quantities are identical for any value of t . Notice that it was essential to have a constant norm of the wave function in order to obtain this result. In the Bianchi I quantum model studied in this paper the analysis follows the same lines, but the norm of the wave function is time-dependent and the equivalence exhibited here is no longer valid.
